

Ammonites

Ammonites are a group of extinct marine mollusc animals with a tightly coiled shell. These creatures lived in the seas from at least 400 to 65 million years ago, when they became extinct. If you are lucky enough to find an ammonite fossil, it will be at least 65 million years old!

Have a look for some photographs of ammonites and, using your shading skills from last week's art lesson, sketch some of them – make sure you add lots of the fine details. I wonder if you can fill a whole page with different drawings of ammonite fossils and what they would have looked like when they were alive?

I'd love to see some photographs of your sketches so send them to your class remote learning email address -
